(57) **ABSTRACT**

The present disclosure relates to a sealing element for hollow sections, including a seal carrier that extends along a longitudinal axis and has two arms each of which has an outer face and an inner face and which are connected together, as one piece, at longitudinal edges that face each other such that they form a corner angle between them seals mounted on or near a free longitudinal edge of each arm and running parallel to the free longitudinal edge, on the outer face of the associated arm, and a securing device, on at least one inner face of an arm, for detachably securing the sealing element onto a corner of a hollow section. A cover cap serves to complete the sealing elements, the cap being provided, on its outer face, with one or more sealing sections designed to connect to ends of the seals of the sealing element.

Fig. 5

1

SEALING ELEMENT AND A SEALING SYSTEM FOR HOLLOW SECTIONS

The invention relates to a sealing element for hollow sections and also to a sealing system for hollow sections which comprises such sealing elements.

Hollow sections, which may consist of metal or plastic for example, are suitable for manufacturing frames and racks such as are needed in various fields of application, for instance in the electrical industry (e.g. as frame elements for switch cabinets), in machine and plant construction (for instance as a machine under-frame or the like), but also in the furniture industry (for example for rack systems and the like). Hollow sections of the aforesaid type may be shaped from sheet metal, but said sections may also be continuous castings (made of aluminium or plastic, for instance). Irrespective of the way in which they are manufactured and the material of which they consist, the hollow sections, which are usually elongated, nevertheless have to be connected, at their ends, to other hollow sections in order to form, for example, a frame, a rack or the like.

It is often necessary for a rack or frame consisting of hollow sections to be provided with side parts in order to create a closed interior space within the frame or rack. If this interior space is to be sealed off from the environment, seals have to be provided between each wall element and the hollow section to which it is secured. For this purpose, it is possible, for example, for each wall element to be provided, on its inner face that faces towards the hollow section, with a seal which comes into sealing abutment with the hollow section when the wall element is secured, or else a seal with which the wall element comes into contact for sealing purposes may be present directly on the hollow section.

The underlying object of the invention is to indicate a solution which is simple to assemble and convincingly functional and which makes it possible to selectively equip a hollow section with a seal in order, for example, to prevent the ingress of dust and/or moisture into an interior space formed by an arrangement of hollow sections, it being optionally possible, in addition, to permit electromagnetic screening as well (in order to obtain so-called "electromagnetic compliance", referred to as "EMC" for short).

This object is achieved, according to the invention, by means of a sealing element for hollow sections which comprises a seal-carrier that extends along a longitudinal axis and has two arms, each of which has an outer face and an inner face and which are connected together, as one piece, at longitudinal edges that face each other, such that they form a corner angle between them, wherein said sealing element further comprises seals mounted on or near a free longitudinal edge of each arm and running parallel to said free longitudinal edge, on the outer face of the arm in question, and wherein said sealing element finally has a securing device, on at least one inner face of an arm, for detachably securing the sealing element on a corner of a hollow section.

According to the invention, therefore, sealing which is necessary is not provided on a wall element which is to be secured, and not even directly on a hollow section itself. Instead, any sealing which may be necessary is achieved by means of an additional sealing element which can be secured to a corner region of a hollow section and is provided on its outer face, on or near the free longitudinal edges, with seals which bring about desired sealing between a hollow section and a wall element which is to be secured to it. According to the invention, sealing elements may be manufactured as material which is sold by the meter and may be made up beforehand in any desired length. Hollow sections which are

2

intended to be provided with sealing later on are no different, according to the invention, from hollow sections of this kind which are used without sealing. Instead, it is possible to decide, according to requirements, whether sealing is to be present or not, by either using, or refraining from using, sealing elements according to the invention. Sealing may optionally also take place afterwards, in which case all that is necessary is to take off wall elements that have already been fitted to a hollow-section frame, and to re-secure them after attaching the sealing elements.

In some forms of embodiment of sealing elements according to the invention, the free longitudinal edge of each arm may be coated with a sealing material, for instance with a suitable elastomer material. In this way, sealing is brought about both on the outer face and on the inner face of each arm. In other forms of embodiment, the seals are mounted only on the outer face of the arm in question. The seals may be attached to the arm by bonding, clamping, fusion or some other suitable method of attachment.

The securing device on the inner face of at least one arm, by means of which device the sealing element as a whole can be secured on a corner of a hollow section, may function, for example, after the manner of a hook-and-loop fastener, may be brought about by plug-in or latching connections between the sealing element and the hollow section, or may be brought about by bonding or even by mechanical securing means such as screws or the like.

In one preferred configuration of a sealing element according to the invention, the two arms consist of elastic material and the corner angle formed between said two arms is slightly smaller than a corner angle which is formed by that corner of the hollow section on which the sealing element is to be secured. If, for example, the hollow section has a corner region with a 90-degree angle, the corner angle of the sealing element is slightly smaller than 90 degrees in this form of embodiment. In a form of embodiment of this kind, the securing device is formed by at least two clamping surfaces, of which one is constructed, in each case, on the inner face of each arm. Each clamping surface extends, at a distance from the longitudinal edges of the arms that face one another, parallel to the longitudinal axis of the sealing element, a clamping angle being formed between the clamping surface and the inner face of the arm in question. Each clamping surface is thus configured in order to interact with a complementary bearing surface on the outer face of the hollow section. Because the corner angle formed between two arms of the sealing element is slightly smaller than the corner angle of the hollow section, the two arms are forced apart slightly when the sealing element is pressed onto the corner region of the hollow section, as a result of which a tensioning force is generated which attempts to re-establish the original state and therefore presses each clamping surface of the sealing element against the associated bearing surface on the hollow section. In this way, the sealing element is held on said hollow section in a clamping manner.

In some forms of embodiment of the sealing element according to the invention, at least one seal is arranged in a longitudinally extending recess on the outer face of the associated arm, one longitudinal edge of said recess, which is closer than the other edge to those longitudinal edges of the arms which face one another and at which the two arms are connected together, being formed by the rear face of the clamping surface of the said arm. In this way, the rear face of the clamping surface forms a lateral support for the seal and, at the same time, ensures satisfactory positioning of said seal. The other longitudinal edge of the recess may likewise perform a supporting and positioning function; however it need

not do so, but may also be arranged in one plane with the free longitudinal edge of the arm in question.

According to one preferred further development of a sealing element according to the invention, there protrudes, from the outer face of at least one of the arms, a web which extends parallel to the longitudinal axis and forms, between itself and the outer face of the associated arm, a spring angle of less than 90 degrees. Said web therefore normally does not protrude in relation to the outer face of the arm, but is inclined towards one or other longitudinal edge of said arm, preferably towards the longitudinal edge at which the two arms are connected together as one piece. This being the case, the web is arranged in such a way that the seal, which is likewise arranged on the arm, is located closer to the free longitudinal edge of the associated arm than the web is. What is achieved in this way is that, when the sealing element is in the fitted state, the seal is located, as it were, behind the web, and the latter is therefore able to protect the seal against, for instance, mechanical damage, liquid impinging in a jet-like manner, etc. The amount by which the web protrudes is preferably chosen in such a way that a wall element which is to be secured comes into contact with the free longitudinal edge of the web first, and only after that, i.e. in the course of the further attachment of the wall element, with the seal which is located on the web. Said web is therefore pressed slightly in the direction of the sealing element by a wall element which is to be secured, as a result of which its free longitudinal edge rests elastically, in a resilient manner, against the inner face of the wall element.

If, in addition to sealing against, for example, dust and/or moisture, further protection against electromagnetic radiation (EMC) is desired, a sealing element according to the invention preferably consists of an electrically conductive material, for instance a metal or an electrically conductive plastic. Alternatively it is possible, if the sealing element consists of a material which is not electrically conductive, to apply an electrically conductive coating to its outer face, including the seals. This may be a film which is applied in a suitable manner, but the electrically conductive coating may preferably be vapour-deposited. Irrespective of the previously described embodiments ensuring electrical conductivity, it is thus achieved that the interior space, which is formed by the arrangement of hollow sections, is protected after the manner of a Faraday cage if the wall elements to be secured are likewise electrically conductive.

If the material from which the sealing element according to the invention is to be manufactured is suitable for being extruded, preferred forms of embodiment of sealing elements according to the invention are designed as a so-called "2C extruded part". What is meant by the term "2C extruded part" is a part which is manufactured by means of a single extruding operation and the material of which consists of two components, of which one component is a fairly hard and stable material which forms the seal-carrier, including any webs that protrude from it, and of which the second component is a resiliently elastic material from which the seals are formed. These two-component extrusion processes are known to persons skilled in the art, so that there is no need to explain in greater detail here how such an extrusion process can be carried out.

If frames or racks are formed from hollow sections, use may be made, for the purpose of connecting a number of hollow sections to the corner of a frame or rack, of so-called "corner connectors" such as are described, for instance, in the German patent application by the same Applicant entitled "Corner connectors for hollow sections". So that satisfactory sealing and, if desired, protection against electromagnetic radiation (EMC) is guaranteed, even in such corner regions,

use may be made according to the invention, in each of the said corner regions in which a number of hollow sections are connected by means of a corner connector, of a cover cap which is provided, on its outer face, with one or more sealing sections which are constructed for connection to ends of the seals which are present on the sealing element. Sealing elements according to the invention and at least one cover cap according to the invention thus form a sealing system for hollow sections which is simple to assemble and dismantle and offers all-round protection against unwanted environmental influences. Each cover cap is preferably configured in such a way that it can be slipped onto the corner connector, the outer surfaces of said cover cap being located in the same plane as adjacent surfaces of the hollow sections which are connected by means of the corner connector. The outer faces of the cover cap thus constitute a continuation of the development of the hollow-section surfaces and form the actual corner of the frame or rack. For the purpose of connection to the seals of a sealing element, the sealing sections mounted on the outer face of the cover cap may have extensions which can be introduced into an inner cavity in a seal belonging to a sealing element.

A cover cap according to the invention, including the sealing sections present on it, preferably consists of an electrically conductive material, so that protection against electromagnetic radiation (EMC) is made possible. Alternatively, an electrically conductive coating may be applied, for this purpose, to the outer face of the cover cap, including its sealing sections.

A currently preferred embodiment of a sealing system according to the invention for hollow sections will be explained in greater detail below with the aid of the appended diagrammatic drawings, in which:

FIG. 1 shows a sealing element for a hollow section, in a three-dimensional representation;

FIG. 2 shows an end view of the sealing element from FIG. 1;

FIG. 3 shows a cross-section through a hollow section with a sealing element according to FIG. 1 mounted on it, two wall elements also being secured to said hollow section;

FIG. 4 shows a cover cap for completing sealing that has been achieved by means of sealing elements from FIG. 1; and

FIG. 5 shows a three-dimensional exploded representation of a frame corner region consisting of three hollow sections which are connected together by a corner connector.

FIGS. 1 and 2 show a sealing element, which is designated generally by 10, for a hollow section 12 such as is represented, for example, in FIGS. 3 and 5. As can be seen in FIG. 2, the sealing element 10 is intended to be attached to a lateral edge 14 of the hollow section 12, which edge forms a corner.

The sealing element 10 has a seal-carrier 16 which extends along a longitudinal axis A and is formed from two arms 18, 20 which each have an outer face 22 and an inner face 24. The two arms 18, 20 are connected together, as one piece, at longitudinal edges that face each other, such that they form a corner angle α between them which, in the embodiment shown, is slightly smaller than 90 degrees.

Mounted on the outer face 22, adjacent to a free longitudinal edge 26 of each arm 18, 20, is a seal 28, 30 which runs parallel to the longitudinal axis A, and thereby parallel to the free longitudinal edge 26, and the function of which will be further explained in greater detail later on. In the embodiment shown, each seal 28, 30 is received and supported in a longitudinally extending recess 32.

Parallel to an inner longitudinal edge of each recess 32 that is closer to those longitudinal edges of the arms 18, 20 which are connected together, a web 34 projects upwards, close to

5

the seal **28** or **30**, from the outer face **22** of the arm **18** or **20**, respectively. Said web **34** runs parallel to the longitudinal axis A and thereby parallel to the seal **28** or **30**, respectively, and is so arranged that a spring angle γ of less than 90 degrees is formed between said web and the outer face **22** of the arm **18**, **20** in question. The function of the said webs **34**, which, in an un-deformed state, jut out slightly beyond the associated seal **28**, **30**, will be explained further.

Constructed, in each case, on the inner face **24** of each arm **18**, **20** is a clamping surface **36**, **38** which is arranged obliquely in relation to the associated arm and which runs parallel to the longitudinal axis A, at a distance from those longitudinal edges of the arms **18**, **20** which are connected together, and forms a clamping angle β between itself and the inner face **24** of the respective arm **18**, **20**. As will be further explained later on, the said clamping surfaces **36**, **38** interact with bearing surfaces **40**, **42** on the outer face of the hollow section **12** in order to secure the sealing element **10** to said hollow section **12**. In the embodiment shown, those rear sides of the clamping surfaces **36**, **38** which are located on the outer face **22** form the inner longitudinal edge of the recesses **32**.

Basically, the seal-carrier **16** may be manufactured from a series of different materials. For example, the seal-carrier **16** may be a part made of steel or even an aluminium section or a section made of some other metal. The seals **28**, **30** may be separate components which are inserted in the recesses **32**, or are securely clamped or securely bonded within them. Other methods of attachment for the seals **28**, **30** are likewise possible.

In the embodiment shown, the seal-carrier **16** consists of a stable and, at the same time, elastic plastic which is suitable for the particular intended application and which is manufactured, together with the seals **28**, **30**, as a so-called "two-component extruded part". This being the case, the seals **28**, **30** consist of a different material from the seal-carrier **16**, preferably of an elastomer material which is known for manufacturing elastic seals. Because of the integrated extrusion process, by means of which both the seal-carrier **16** and the seals **28**, **30** are produced together, said seals **28**, **30** are already fused to said seal-carrier **16** because of the temperature prevailing during extrusion, and no longer need to be attached separately. By means of a two-component extrusion process of this kind, sealing elements **10** can be manufactured, as it were, continuously and be cut to desired lengths afterwards.

The function of sealing elements **10** will now be explained in greater detail with particular reference to FIGS. 3 and 5. In this connection, FIG. 5 shows three hollow sections **12** which are arranged in pairs at right angles to one another and form the corner of a frame, of which no further details are represented. For the purpose of connecting the three hollow sections **12** in the corner region, use is made, by way of an example, of a corner connector **44** such as is shown and described in the German patent application by the same Applicant entitled "Corner connectors for hollow sections", but which may also be of a different design so long as it is ensured that said corner connector connects the three hollow sections **12** together in a reliable and stable manner.

FIG. 3 shows a section through the hollow section **12**, which is the lower one in FIG. 5, outside the region in which the corner connector **44** is arranged, and reveals that, in the finished state, wall elements **46**, which close an interior space surrounded by the frame, are secured externally to the hollow sections **12**. The said interior space is reliably screened against environmental influences by means of the sealing elements **10**.

6

In order to obtain the desired sealing, a sealing element **10** is attached to the lateral edge **14** of each hollow section **12**, as represented in FIG. 5. Since, in the example shown, the corner angle of the hollow sections amounts to 90 degrees, but the corner angle α of the sealing elements **10** is slightly smaller, said sealing elements **10** are expanded slightly on being slipped onto the hollow sections **12**, i.e. the arms **18**, **20** are pressed apart slightly. Because the material of which the seal-carrier **16** consists is elastic, this expansion results in a spring force which forces the arms **18**, **20** towards one another and thereby presses the clamping surfaces **36**, **38** on the inner face **24** of the sealing element **10** against the bearing surfaces **40**, **42** on the hollow section **12**. By means of this clamping action, each sealing element **10** is held on the hollow section **12** in a secure yet easily detachable manner.

The assembled state of a sealing element **10** is visible from FIG. 3. It can be seen that the inner face **24** of the sealing element **10** is constructed in a manner complementary to the outer face of the hollow section **12**, so that the sealing element **10** clings to said outer face of the hollow section **12**. As soon as the sealing element **10** is mounted on the hollow section **12**, the seals **28**, **30** are automatically located in a position in which they can come into contact with the inner face of the wall elements **46**.

When a wall element **46** is secured to the hollow section **12**, the inner face of said wall element **46** first of all comes into contact with the free edge of the web **34**. In the course of further securing of the wall element **46**, which takes place, for example, by tightening screws which are not represented here, the distance between the inner face of the wall element **46** and the outer face **22** of the sealing element **10** is reduced, so that the web **34** is deformed slightly, as a result of which the spring angle γ is slightly diminished. When the wall element **46** is completely secured to the hollow section **12**, therefore, a spring force, which presses the free longitudinal edge of the web **34** against the inner face of the wall element **46** and in this way forms initial sealing, for example against splashes of water, operates within the web **34** which consists of the elastic material of the seal-carrier **16**. When the wall element **46** is in the state in which it is completely secured to the hollow section **12**, the outer face of the seals **28**, **30** is also in resilient contact with the inner face of the wall element **46** in question, thereby forming second sealing which constitutes the actual sealing. In the embodiment shown, each seal **28**, **30** is formed by a hollow section of the seal that has, on its outer face, two sealing lips **48**, **50** and, between them, a convexly curved sealing region **52**, the outer face of which, when in the fitted state, is in linear or strip-shaped contact with the inner face of a wall element **46**.

Also shown, in FIGS. 4 and 5, is a cover cap **54** which completes sealing that is achieved by means of the sealing elements **10**. Said cover cap **54** consists of three wall sections **56**, **58**, **60** which are connected together as one piece and at right angles to one another and on the outer face of which there is secured, in each case, a sealing section **62**, **64**, **66**, of which only the sealing sections **62** and **64** are visible in FIG. 5. The material from which the wall sections **46**, **58**, **60** of the cover cap **54** are formed, may be the same material from which the seal-carrier **16** of the sealing elements **10** has also been manufactured; however, use may also be made of a material which is different from that of said seal-carrier **16**. The wall sections **56**, **58**, **60** may, for example, also consist of metal, although the material of the seal-carrier **16** is a plastic in the embodiment shown. The material of which the sealing sections **62**, **64**, **66** consist is preferably the same material from which the seals **28**, **30** are also produced.

The cover cap **54** is configured in order to be secured on the corner connector **44**, for example by latching. In the state in which they are secured to the corner connector **44**, the wall sections **56, 58, 60** of the cover cap **54** substantially constitute a continuation of the relevant outer surfaces of the hollow sections **12** that have been connected together by means of the corner connector **44**. The actual corner of the frame formed by the hollow sections **12** is thus located on the cover cap **54** at the point at which all three wall sections **56, 58, 60** meet.

As is represented, the sealing sections **62, 64, 66** are of curved design in such a way that they each connect together two seals **28** or **30** of adjoining sealing elements **10**. In order to produce a reliable connection between the sealing sections **62, 64, 66** and associated seals **28, 30**, the ends of each sealing section **62, 64, 66** are each provided with a projection **68**, which can be introduced, when the cover cap **54** is secured to the corner connector **44**, into a cavity **70** which is formed by the sealing section of which the seals **28, 30** consist.

Cover caps **54** provided with the sealing sections **62, 64, 66** may be used to advantage on a frame formed from hollow sections **12**, even when no sealing elements **10** are used, because said sealing sections **62, 64, 66** may then serve, e.g., as soft stops for a door, for example, which is secured to the frame.

The invention claimed is:

1. A sealing element for hollow sections, comprising:

a seal-carrier that extends along a longitudinal axis and has two arms, each arm having an outer face and an inner face and the two arms being-connected together, as one piece, at longitudinal edges that face each other, such that they form a spring angle slightly smaller than 90 degrees between them;

seals which are mounted on or near a free longitudinal edge of each arm, in a manner running parallel to the free longitudinal edge, on the outer face of the corresponding arm; and

at least two clamping surfaces forming a clamping device each of the at least two clamping surfaces on the inner face of a corresponding one of the arms, each of the at least two clamping surfaces extending a distance from the longitudinal edge of the corresponding arm parallel to the longitudinal axis, each of the at least two clamping surfaces forming an obtuse clamping angle with the inner face of the corresponding arm.

2. The sealing element according to claim 1, wherein the two arms consist of elastic material, and wherein the spring angle is slightly smaller than a corner angle which is formed by a corner of the hollow section on which the sealing element is to be secured.

3. The sealing element according to claim 1, wherein each seal is arranged in a longitudinally extending recess on the outer face of the corresponding arm, one longitudinal edge of the recess, which edge is closer to those longitudinal edges of the arms that face one another, being formed by the rear face of the clamping surface of the arm.

4. The sealing element according to claim 1, wherein there protrudes, from the outer face of at least one of the arms, a web which extends parallel to the longitudinal axis and forms, between itself and the outer face of the corresponding arm.

5. The sealing element according to claim 1, wherein the sealing element consists of an electrically conductive material.

6. The sealing element according to claim 1, wherein an electrically conductive coating is applied to its outer face, including the seals.

7. The sealing element according to claim 6, wherein the electrically conductive coating is vapour-deposited.

8. The sealing element according to claim 1, wherein the sealing element is designed as a 2C extruded part.

9. A sealing system for hollow sections, comprising:

at least two sealing elements according to claim 1; and at least one cover cap which is provided, on its outer face, with one or more sealing sections which are constructed for connection to ends of the seals belonging to the sealing element.

10. The sealing system according to claim 9, wherein the cover cap, including its sealing sections, consists of an electrically conductive material.

11. The sealing system according to claim 9, wherein the cover cap consists of an electrically conductive coating applied to the outer face of the cover cap, including its sealing sections.

12. The sealing element according to claim 1, wherein the clamping device is configured to detachably secure the sealing element on a corner.
